

INJURIES OF OROFACIAL REGION IN CHILDHOOD

Kasza Barbara

Szegedi Tudományegyetem Fogorvostudományi Kar, egyetemi hallgató

Nowadays after an injury has occurred, patients get treated but they do not get any advice on preventing these injuries. Even the most precise dental work cannot replace someone's natural teeth which can cause mental and bodily traumas. Babies, children and adolescent are the most common age group related to this area's injuries during playground activities, sports or work out.

Children between age 3 and 18 spend most of their time at school, hence getting hurt usually happens in these institutes. I conducted a survey among Hungarian teachers to find out how much they really know about orofacial traumas and also if they know how big their role is related to treatment of these injuries.

Hopefully in the future we could make a course where teachers could learn about helping injured kids. Also, using social media network or placing posters and pamphlets in school could popularize prevention.

Keywords: *injuries in childhood, orofacial injuries, orofacial traumas, prevention*
